

ATR NUMBER:	26-008	PROJECT NO.:		DATE:	7/28/2026
ORIGINATOR:	Shaun Sekura			MANAGER:	Bob Wheeler
PROJECT:	Summer 2026 V&VT Internship				
REPORT SUBJECT:	End of Internship Report				
KEYWORDS:	Cord, Compound, Bimodal, MTS-810, Abaqus, T360				
cc:	ATC Web, ARENA				

Executive Summary

Summary:

This session included 4 projects. The first project objective was to study the current methodology used to assign moduli to cords and compounds in Hankook's database, then validate the use of a more accurate modulus calculation to produce more accurate performance predictions with FE models. The modulus data from nylon and polyester cords was first specifically used for finite element (FE) virtual inflated shape accuracy study. The current method of calculating cord modulus is a linear regression slope of a full stress-strain curve, an engineering assumption that the stress-strain curve is linear to simplify calculations. The resulting new data produced a nonlinear cord modulus that was lower than the current linear version for both the nylon and polyester. To analyze the physical data, a second project was used in which a custom T360 surface measurement data processor was created in Python. The physical and virtual inflated profile data at 180 kPa were compared. Then the new cord data was used in the FE model and a new virtual profile was predicted. An average improvement of 50.4% at tire crown ribs and groove bases. For the second part of the first project compound bimodal moduli were reviewed to understand the logic behind the derivation of modulus from complex harmonic stress-strain testing and find any additional nonlinearities to consider for future implementation. Along with these two projects, two smaller projects included a physical tire footprint camber validation investigation and a wheel CAD FE meshing and mode shape study.

Forward Plan:

Additional research may be required to determine conclusions of improved modulus at the side of the tire profile. The T360 processor program made by me only works for the top half of the tire profile and causes an intersection with the VTA profile at the side of the tire profile. A better T360 processor could be used to further test this conclusion. If this conclusion is proven right, a refined cord database would allow for more accurate profiles.

Table of Contents

- 1) Introduction**
- 2) Development / Misc. Projects**
- 3) Cord and Bimodal Compound Project**
- 4) Inflated Tire P-V Analysis**

1) Introduction

Education

Rising Junior at The Ohio State University

- Bachelor of Science in Mechanical Engineering (12/27)

THE OHIO STATE UNIVERSITY
COLLEGE OF ENGINEERING

Work Experience

Summer 2026 Co-op with Hankook Tire & Technology

- Worked in Virtual & Validation Department under Bob Wheeler
- Returning to Ohio State to continue studies
- Previous experience with EcoCAR and Formula SAE teams at Ohio State

Summer 2026

Fall 2025 – Spring 2026

Fall 2024 – Spring 2025

2) Development / Misc. Projects

ATRs Read:

- ATR 08-024: Material Characterization for Rolling Tire Modal Analysis
- ATR 04008: Material Characterization at Modal Test Strain Levels
- ATR 09-041: PCI Modeling Accuracy Improvement
- ATR 16-015: Previous Intern Project

- ❑ Tutored on Abaqus, Hypermesh, and Python for virtual applications
- ❑ Tutored on Siemens Test Lab (free-free & fixed free modal testing) and FPM Machine for physical applications
- ❑ Read ATRs to understand previous work and project writing

Cord Datasheet

Compound Datasheet

Most ATRs were read to supplement the cord and bimodal compound project and understand where the data came from.

2) Development / Misc. Projects

❖ Full CAD Wheel

❖ Trimmed CAD Wheel Web

❖ Frequency Mode Shapes
w/ wheel fixed by bolt holes

- Virtual applications using OE Wheel
- Used Hypermesh to trim wheel and mesh wheel within tolerances
- Used Abaqus to apply loads and frequency to observe mode shapes

2) Development / Misc. Projects

- Footprint pictures taken with FPM Machine
- Analysis done with FP Characterization program
- Data taken at combinations of
 - 350 kg, 678.1 kg, 863.2 kg, 1360 kg
 - 60 psi, 65 psi, 70 psi, 80 psi
 - 3 degree camber, -3 degree camber

- Max lengths percent difference: 1.951%
- Average lengths percent difference: 3.033%
- Confidence in symmetrical camber being interchangeable

Vehicle Footprint Test	Load: 350 kg / Camber: 3 deg				Load: 678.1 kg / Camber: 3 deg

=SLOPE(K12:K111,J12:J111)

- Current method finds modulus by taking the linear regression slope
- Good method for linear analysis, modulus is approximately linear, but still nonlinear
- Set up method to adjust modulus based on given strain

Bimodal Compound

- Current method samples modulus only at one rolling freq. at one vibratory strain at one harmonic freq. & one base strain
- Set up method to adjust modulus based on rolling freq. and vibratory strain

3) Cord and Bimodal Compound Project

Cord Creep Test Stand

Cords with tests at room temperature (~20° - 30° C) were selected for this study

Each cord was analyzed at 2 load ranges

300~400ea/ply

3) Cord and Bimodal Compound Project

1. Least squares linear regression slope of stress strain to calculate strain vs. moduli, noisy data

3) Cord and Bimodal Compound Project

2. Trend line to curve fit stress strain graphs

3) Cord and Bimodal Compound Project

3. Take derivative of trend line to curve fit against moduli

3) Cord and Bimodal Compound Project

4. Normalize about original constant modulus for comparison

3) Cord and Bimodal Compound Project

Dimensional Stable Polyester at lower loads (in red) were excluded

Behavior caused by nature of dimensional stability

- Lower loads: heat-set structure & internal stresses affect strain vs. moduli relationship
- Higher loads: stabilizing treatment is overcome and behavior follows trend

Average of strains vs moduli

Establishing a relationship between percent strain and modulus

- FORECAST.LINEAR() to interpolate values
- AVERAGE() to take average at each interpolated point

Nylon and polyester modulus samples were combined due to similarity of normalized modulus

3) Cord and Bimodal Compound Project

For averaged slope of strain vs moduli graphs:

- At 0.1% strain, modulus is on average 15% lower
- At 1.0% strain, modulus is on average 15% higher

New Proposed Method: Use equations for each cord for more accurate modulus

Next Steps: apply to cord database to expand the data, apply to more cords to observe relationship

3) Cord and Bimodal Compound Project

Single sine

Single sine		1				
Condition	Amplitude	Hz.	K*	K'	K''	TanD

Dynamic Stiffness: $K^* = \frac{F_o(f_1)}{\delta_o(f_1)}$; stiffness measured at primary (slow) frequency

Harmonic Dynamic Stiffness: $\text{Harm } K^* = \frac{F_o(f_2)}{\delta_o(f_2)}$; stiffness measured at fast frequency

Phase (φ_1); time lag/response delay to loading at slow frequency

Harmonic Phase (φ_2); time lag/response delay to loading at fast frequency

Mono-modal vibratory modulus ($\overline{E'_{mv_i}}$) and Alpha (α)
Bi-modal vibratory modulus (E'_{bv,adj_i}) and Beta (β)

3) Cord and Bimodal Compound Project

❖ Image from previous 2016 study

Dynamic Stiffness Amplitude (from Sine on sine data)

Phase (from Sine on sine data)

thickness

length

width

Shear modulus to young modulus conversion

$G = \frac{E}{2(1 + \nu)} \rightarrow E = 3G$

$\frac{N}{mm} = \frac{lbs}{in}$

quad lap

$$E'_{bv} = K^* \cdot \cos(\theta \cdot \frac{\pi}{180}) \cdot \frac{5}{40 \cdot 15} \cdot 0.175127 \cdot 3 \cdot \frac{1}{4}$$

3) Cord and Bimodal Compound Project

- Datasets exist from two prior studies (2007, 2016 – above data)
- Current FE process only samples at one rolling frequency, one vibratory strain & frequency
- 2016 data also has lower harmonic strain, indicates more significant beta
- New method: select rolling frequency & vibratory strain, provides more accurate modulus

4) Inflated Tire P-V Analysis

Physical vs virtual comparison of GM 9BUX Tire at 180 kPa, 27° Belt Angle

- Physical: T360 Tire Scanner
- Virtual: VTA (no mold lift)

❖ OE Dev Tire on a OE Wheel during Free-Free test – Allen Basker

4) Inflated Tire P-V Analysis

4) Inflated Tire P-V Analysis

- Windowing by chunks and groups
- Centered at zero to match other files
- Modifiable outliers for fine tuning
- Searchable y values from x with interpolation for analysis against virtual files

4) Inflated Tire P-V Analysis

Total Run Time: 71.49 sec

Average Deviation at Crown: 0.862 mm

Average Deviation in Grooves: 2.853 mm

Windowing by groups: 66.97 sec

Average Deviation at Shoulder/Sidewall: 0.514 mm

4) Inflated Tire P-V Analysis

Modified input files data for inflated shape comparison

- Nylon (cap)
- Polyester (carcass)

FE cord component properties updated

Table with multiple columns and rows, showing data for various components. A large section of the table is highlighted in yellow, indicating modified data. An arrow points to this section with the text "stress-strain properties modified".

4) Inflated Tire P-V Analysis

Average improvement of 50.4% at grooves

Hard to tell at sides due to T360 processor limitations and aforementioned intersection

Validate importance of lower strain range in Abaqus/VTA input files

Next steps: Check relationship at other inflations, green angles, mold lift, determine if relationship holds at sides of tire profile using better T360 processor, refine cord database if conclusion further proven

	VTA Deviation	Cord Modified Deviation	Percent Difference
Leftmost Groove	0.71 mm	0.445 mm	+37.3%
Center Left Groove	0.679 mm	0.363 mm	+46.5%
Center Groove	0.422 mm	0.138 mm	+67.3%
